Overview of Further Research

Mobile cryptography Black-box Security Practical Approach

Summary

What do we want to get?

We want to be sure that our system is safe to use.

In lecture 4 "Applications of Obfuscation" we'll discuss what kind of safety we want to get by obfuscation.

Today: what does it mean to be sure about safety?

Usual approach: to build some proof of safety.

computation

Overview of Further Research

Mobile cryptography Black-box Security Practical Approach

Summary

How are we going to prove security?

Theoretic security: obfuscated program doesn't provide enough information to successful attack Example: exact reverse engineering. Solution: delete comments

Ways to Security

➡ Computational (cryptographic) security: attack required too much computation

Necessary hardness of attack: average superpolynomial complexity. Now: no problems with such proved complexity

Summary

One-Way Permutation is bijection from the set of all binary strings of length k to itself which is easy to compute and difficult to inverse.

$$F: B^k \to B^k$$

Hardcore Predicate for one way permutation F is a predicate (i.e. boolean function) h such that given F(x) its difficult to predict h(x) better than just guess it.

Usual construction of hard-core predicate: choose *r* by random and take any one way permutation *F* than given a pair (F(x), r) its difficult to uncover $x \cdot r$.

Homomorphic Encryption

General idea: to design an encoding such that it is possible to evaluate various operations over encrypted messages (and getting encrypted results) without decrypting them.

In particular encoding is called

- ⇒ Additively homomorphic if it is possible to compute E(x + y) from E(x) and E(y)
- $\Rightarrow Multiplicatively homomorphic if it is possible to compute <math>E(xy)$ from E(x) and E(y)
- \Rightarrow Mixed multiplicatively homomorphic if it is possible to compute E(xy) from E(x) and y.

Summarv

Let *P* be polynomial over $\mathbb{Z}/N\mathbb{Z}$ ring.

$$\mathsf{P} = \sum \mathsf{a}_{i_1 \ldots i_s} X_1^{i_1} \ldots X_s^{i_s}$$

Then we can encrypt P by just sending encrypted coefficients (using MM-A homomorphic encryption). Bob is able to compute E(P(X)) and return it back to Alice.

What we reveal to Bob? Only set of nonzero coefficients of Ρ.
